The Paradigm Shift

April 2026

Disclaimer and Credits

Author's Disclaimer and Request for Verification

These classical information-theoretic frameworks—Shannon's, Gabor's, and von Neumann's theories—are several levels above my pay grade. I do not claim to have understood even one line of their physical descriptions, let alone the equations. The integration presented in this chapter has been constructed strictly according to the operational logic of the event-based model and the fundamental Operational Axiom of Entanglement.

Drafting by AI (Grok/Gemini/Chat GPT)

All chapters were drafted by an AI system (Grok) under my explicit instructions and is based on my own understanding—or lack thereof—of the situation. I am being brutally honest in acknowledging the limits of my expertise in these areas. I therefore warmly invite rigorous verification, critique, and improvement by experts in information theory, quantum foundations, and signal processing. Any errors or inaccuracies are mine alone, and I welcome corrections that remain faithful to the minimal event-based reformulation and the Operational Axiom.

Abstract

This book presents a minimalist event-based reformulation of information and a complete system blueprint for its manifestation. Information is defined as the occurrence of a structureless event—its binary presence (1) or absence (0) within a synchronized clock interval n—carrying exactly 1 bit when probabilities are equal. Transmission is the reliable detection of such an event, achieved through synchronized clocks and redundant channels with majority voting.

In the quantum domain the framework rests on a single Operational Axiom of Entanglement: a local classical action performed on one part of an entangled system instantaneously and deterministically manifests as the corresponding change on the spatially separated part. Alice and Bob are parts of a single unified non-local quantum state; nothing propagates through spacetime. The manifestation time is therefore exactly zero. This is termed Instantaneous Manifestation of State Change (IMSC).

Classical information theories (Shannon, Gabor, von Neumann) and their associated constraints (Special Relativity, no-signaling theorem, Bell/EPR results) remain fully valid in their original domains and are recovered as special cases when multiple structureless events are aggregated or when the analysis is restricted to local marginals. The framework simply operates in a conceptual domain where those constraints are not required.

The book provides the formal definition, core claims, unification with classical theories, broadcast mechanisms, and a concrete experimental pathway using commercially available off-the-shelf (COTS) components. It invites rigorous experimental validation of the Operational Axiom and the resulting Instantaneous Manifestation of State Change.

Volume I

Implications

Part I
Implications -Technological

Chapter 1
Technological and Practical Consequences

1.1 Revolutionary Communication Systems

Instantaneous Galactic Networks: If the core hypothesis is experimentally validated, communication across astronomical distances could become instantaneous through IMSC on a unified non-local state, enabling real-time coordination of interstellar civilizations, space exploration missions, and astronomical observations.

Quantum Information Processing: Quantum computing and cryptography could exploit the non-local correlations enabled by the Operational Axiom of Entanglement for novel algorithms and security protocols that transcend current theoretical limitations based on propagating signals.

1.2 Navigation and Coordination Paradigms

GPS and Positioning: Current satellite-based navigation systems rely on light-speed signal propagation. If IMSC is realized, precision positioning systems with fundamentally different error characteristics could become possible.

Distributed Computing: Massive parallel processing systems could coordinate instantaneously across global or interplanetary networks through shared non-local states, eliminating latency-based computational bottlenecks.

Part II
Implications - Civilizational

Chapter 2
Societal and Civilization-Level Consequences

2.1 Economic and Social Transformation

Market Dynamics: If the core hypothesis is experimentally validated, financial markets could operate with true global simultaneity through Instantaneous Manifestation of State Change (IMSC) on a unified non-local state, fundamentally altering trading strategies, risk assessment, and economic modeling.

Social Coordination: Human society could achieve unprecedented levels of real-time coordination and decision-making across any spatial scale through the simultaneous detection of a single structureless event by multiple receivers sharing the same entangled state.

2.2 Security and Privacy Implications

Cryptographic Obsolescence: Many current cryptographic protocols rely on the finite time required for information transmission. If IMSC is realized, numerous security measures that depend on propagation delay might become obsolete, while simultaneously enabling new quantum cryptographic protocols based on non-local correlations.

Surveillance Capabilities: The potential for instantaneous, long-distance information gathering through IMSC could have profound implications for privacy, governance, and individual autonomy.

Part III
Implications - Philosophical

Chapter 3
Consciousness and Cognitive Consequences

3.1 Neural Processing and Brain Function

Instantaneous Neural Networks: If consciousness involves quantum processes (as suggested by theories like Orchestrated Objective Reduction), IMSC could enable new forms of neural computation that transcend current biological limitations. Brain-computer interfaces could operate with zero latency, potentially allowing direct neural communication between individuals.

Extended Mind Hypothesis: The philosophical concept of extended mind—where cognitive processes can extend beyond the biological brain to include tools and environment—would be dramatically amplified. Consciousness could theoretically extend across arbitrary spatial distances instantaneously through shared non-local states.

3.2 Collective and Distributed Consciousness

Hive Mind Possibilities: IMSC could enable the emergence of genuine collective consciousness, where individual minds could share thoughts, memories, and experiences in real-time across any distance. This might represent the next stage of human cognitive evolution.

Global Brain Networks: Human civilization could develop into a truly integrated global brain, with individual consciousnesses functioning as neurons in a planetary-scale cognitive system capable of unprecedented problem-solving and creativity.

3.3 Identity and Personal Boundaries

Consciousness Boundaries: Traditional concepts of individual identity and personal consciousness boundaries would be challenged. The question "where does one consciousness end and another begin?" would become practically relevant rather than purely philosophical.

Telepathic Communication: Direct mind-to-mind communication could become possible through IMSC, fundamentally altering human social interaction, empathy, and understanding. Privacy of thought—a fundamental aspect of current human experience—might become obsolete.

3.4 Memory and Experience

Shared Memory Systems: Individuals could potentially access shared memory pools instantaneously through IMSC, creating collective repositories of human knowledge and experience that transcend individual cognitive limitations.

Time-Symmetric Consciousness: If IMSC enables information to influence past events, consciousness might develop temporal extension—the ability to influence or access past mental states, creating new forms of temporal self-awareness.

3.5 Altered States and Expanded Awareness

Cosmic Consciousness: The ability to instantaneously connect with consciousness across vast distances through IMSC might enable new forms of cosmic or universal awareness, where individual consciousness could participate in larger-scale conscious systems.

Quantum Consciousness Networks: If consciousness has quantum mechanical aspects, IMSC could create new forms of non-local conscious experience that transcend classical spacetime limitations.

3.6 Free Will and Decision-Making

Retrocausal Agency: The ability to manifest information in ways that appear to influence past events raises profound questions about free will and moral responsibility. Could conscious decisions influence past events? How would this affect concepts of choice, agency, and ethical accountability?

Parallel Decision Processing: Consciousness could potentially exist in multiple reference frames simultaneously, experiencing different temporal sequences of the same events, leading to new forms of parallel or multidimensional decision-making processes.

3.7 Death and Continuity of Consciousness

Information Preservation: If consciousness can be manifested through IMSC, new possibilities emerge for consciousness preservation, backup, and transfer that could fundamentally alter concepts of death and personal continuity.

Distributed Immortality: Consciousness might become distributable across multiple physical substrates instantaneously through IMSC, potentially enabling forms of cognitive immortality that transcend biological death.

3.8 Consciousness Research Implications

Hard Problem Resolution: The "hard problem" of consciousness—explaining subjective experience—might find new avenues for investigation if consciousness involves non-local information processing that cannot be reduced to classical neural computation.

Observer Effect Amplification: The role of consciousness in quantum measurement could be dramatically amplified if conscious observation can have instantaneous effects across arbitrary distances through IMSC, potentially supporting theories where consciousness plays a fundamental role in physical reality.

Chapter 4
Cosmological and Existential Consequences

4.1 Universe-Scale Implications

Cosmic Communication Networks: If the core hypothesis is experimentally validated, IMSC on a unified non-local state could enable communication with potentially existing extraterrestrial civilizations across galactic distances, fundamentally altering humanity's cosmic perspective.

Information Density: The universe's total information-processing capacity would effectively increase, as widely separated regions could participate in coordinated computational processes through shared non-local states.

4.2 Thermodynamic Considerations

Entropy and Information: The relationship between thermodynamic entropy and information entropy would require re-examination, particularly regarding the second law of thermodynamics and Maxwell's demon-type scenarios.

Energy-Information Equivalence: New relationships between energy, matter, and information might emerge, potentially revealing deeper principles underlying physical reality.

Chapter 5
Scientific and Epistemological Consequences

5.1 Experimental Science Revolution

Real-Time Cosmic Observation: Astronomy would be transformed by the ability to coordinate simultaneous observations across multiple locations instantaneously through IMSC, enabling new classes of experiments in cosmology and astrophysics.

Instantaneous Data Correlation: Scientific collaborations could share and analyze data in real-time regardless of geographic separation, accelerating discovery processes.

5.2 Fundamental Physics Restructuring

New Conservation Laws: The discovery of IMSC would likely reveal new physical principles and conservation laws governing information, energy, and momentum transfer in non-local systems.

Unified Field Theories: Reconciling non-local manifestation with existing physics might require development of new unified theories incorporating higher-dimensional spaces or exotic matter-energy relationships.

Chapter 6
Fundamental Physical Consequences

6.1 Causality Violations and Temporal Paradoxes

Grandfather Paradox Extension: If IMSC enables information to influence events in ways that appear to precede their cause in certain reference frames, it becomes possible under certain relativistic conditions to create closed timelike curves. This enables paradoxical scenarios where an effect could precede and potentially prevent its own cause.

Mathematical Basis: In special relativity, events that are spacelike-separated can have different temporal ordering depending on the reference frame. The possibility of zero-time manifestation raises questions about the structure of spacetime geometry.

6.2 Violation of Relativistic Covariance

Frame-Dependent Physics: Zero-time manifestation via a unified non-local state would require careful examination of whether a preferred reference frame emerges, potentially affecting the principle that all inertial frames are equivalent.

Lorentz Invariance Breakdown: The mathematical structure of special relativity might require re-examination in light of non-local correlations that do not involve propagating signals, while preserving all existing experimental confirmations and theoretical predictions in their original domains.

Chapter 7
Philosophical and Conceptual Consequences

7.1 Determinism and Free Will

Causal Determinism: If the core hypothesis is experimentally validated, the ability to manifest information instantaneously through IMSC on a unified non-local state would challenge fundamental assumptions about determinism, free will, and the nature of temporal progression.

Information-Theoretic Paradoxes: Questions would arise about the nature of information itself—whether it can be truly created or destroyed, and how information conservation interacts with temporal causality.

7.2 Reality and Observation

Observer Effect Amplification: The relationship between observation and physical reality might require complete reconceptualization if observers could instantaneously influence distant events through shared non-local states.

Measurement Problem: Quantum mechanics' measurement problem would be compounded by non-local manifestation, potentially requiring new interpretations of wavefunction collapse and decoherence.

Part IV
The Paradigm Shift

Chapter 8
Review of Key Assertions - Assumptions Invalidated

8.1 Abstract

This chapter reviews the key assertions of the event-based reformulation concerning randomness in quantum measurements, particularly quantum non-demolition (QND) measurements, and their relation to the definition of information as a structureless event ($I(E) = 1$). It examines how traditional interpretations (e.g., von Neumann's collapse postulate) may not be required when non-destructive detection is used, while maintaining full respect for foundational contributions by von Neumann, Einstein, and others.

8.2 Context and Assertions

The event-based framework defines information as the occurrence of a structureless event ($I(E) = 1$) detected reliably through QND and an NV-photon-spin mapper. The assertion is that claims of inherent randomness arising from wavefunction collapse are not required for this operational definition. Similarly, Einstein's causality and light-speed postulates in STR are foundational for propagating signals but may not govern non-local correlations in a unified entangled state.

8.3 1. Randomness Claim and von Neumann's Collapse

Assertion: Claims of inherent randomness due to wavefunction collapse (von Neumann) are not required for the definition of information as a structureless event. QND, widely used in advanced laboratories, preserves observables without collapse, enabling deterministic detection within the clock interval.

Review: Von Neumann's collapse model suggests measurements project the wavefunction to a definite state, introducing randomness — a perspective reflected in discussions by Griffiths (2004) and Monroe (2011). However, the reformulation focuses on information as a single-bit event (e.g., a photon flop mapped to electron spin), detected non-destructively via QND and processed with clock-based sampling. This approach does not invoke collapse, rendering randomness claims associated with it not required in this context.

Analysis: Established results on QND (e.g., Braginsky and Khalili, 1992; Bürgler et al., 2023) highlight its ability to measure without disturbing the observable, aligning with the assertion. In the system, the NV-mapper converts correlations to physical spin changes, detected deterministically, supporting the view that traditional randomness may stem from interpretive assumptions rather than fundamental necessity for this operational definition.

8.4 2. Relation to Foundational Figures

Von Neumann: The collapse postulate remains influential. The event-based framework simply does not adopt it as a necessary premise when QND detection is used.

Einstein: The STR's postulates on causality and light-speed limits are foundational for classical systems involving propagating signals. In the context of a single unified non-local state, the framework operates in a domain where those postulates do not govern the instantaneous manifestation.

Griffiths (2004) and Monroe (2011): Their emphasis on randomness in measurements aligns with standard interpretations. The event-based model offers an operational perspective in which QND enables deterministic event detection, suggesting that certain randomness claims may not be required in this specific context.

8.5 Key Verifications

- **QND and Collapse**: Results confirm QND's non-destructive nature, supporting the assertion that randomness from collapse is not required. Timing NV spin flips via SQUID can demonstrate determinism.
- **Misinterpretation Risks**: Griffiths and Monroe's randomness discussions reflect standard quantum mechanics but may not fully account for QND in event-based systems. Deterministic experiments could clarify the scope.
- **Einstein's Postulates**: Entanglement's non-locality, as verified by Bell tests, extends the domain beyond propagating-signal constraints.
- **Metaphor**: The *Independence Day* scene symbolizes a transitional moment from uncertainty to clarity, illustrating the shift toward accepting non-local realities through empirical testing.

8.6 Discussion Points

1. **Experimental Validation**: A specific experiment, such as timing NV spin flips with SQUID, could confirm deterministic QND detection and address interpretive questions.
2. **Misinterpretation vs. Oversight**: Distinguishing requires examining context — deliberate conservatism or genuine interpretive difference — in these works.
3. **Einstein's Legacy**: The postulates remain essential for classical domains but may be extensible in quantum contexts, respecting their foundational role.
4. **Metaphor Integration**: The *Independence Day* metaphor highlights the transition from uncertainty to clarity through open empirical inquiry.
5. **Causality Principle**: With traditional no-signaling viewed as not governing the unified non-local state, causality is maintained through the event's structurelessness and clock synchronization.

Chapter 9
Paradigm Shift: The Collapse of the Old Empire and the Rise of a New One

The event-based reformulation of information as the occurrence of a structureless event ($I(E) = 1$) and its manifestation through the Operational Axiom of Entanglement represents a potential paradigm shift in physics. This chapter examines that possibility using the historical metaphor of the collapse of an old empire and the emergence of a new one, while maintaining full respect for the foundational contributions of previous frameworks.

Scientific revolutions have often followed this pattern: a dominant paradigm (Ptolemaic astronomy, Newtonian mechanics) is gradually challenged by accumulating anomalies until a new framework (Copernican heliocentrism, quantum mechanics) offers a simpler, more general description. In the present case, the proposed system — a controlled local action inducing a deterministic, instantaneous manifestation on the spatially separated part of a unified non-local state, detected via nitrogen-vacancy (NV) centers and quantum non-demolition (QND) measurements — operates in a domain where certain traditional assumptions are not required. QND measurements, standard in advanced laboratories, preserve observables without invoking projective collapse. The scientific community's cautious stance toward such ideas is understandable and reflects a transitional moment familiar from past revolutions.

9.1 Gaping Cracks in the Fortress Walls: Analyzing Key Challenges

The no-signaling theorem, grounded in the assumption of structured data and propagating signals ($I(X : Y) = 0$), may not fully govern the reformulation's structureless events, which require only single-bit detection via NV-mapper and SQUID. Similarly, STR's light-speed limit, which assumes electromagnetic propagation, appears as a constraint that does not apply to entanglement's non-local correlations, which involve no energy transfer between separated parts of the unified state. QND measurements challenge the necessity of von Neumann's collapse model by enabling deterministic outcomes through clock-based sampling at interval n, registering binary results (1 for flop, 0 otherwise). Discussions by Griffiths (2004) and Monroe (2011) reflect standard interpretations of measurement but may not fully account for QND's capabilities in modern setups. Einstein's causality postulates (1905) remain foundational for classical propagating-signal systems but may not govern the instantaneous manifestation in a unified non-local state.

These observations are not presented as refutations of established principles in their original domains. They simply highlight that the event-based framework operates in a conceptual space where those assumptions are not required.

9.2 Does Success Require Overturning Established Principles?

The core hypothesis directly engages with principles of quantum mechanics and special relativity. A structured analysis follows:

1. **Quantum Mechanics and the No-Signaling Theorem**

- The no-signaling theorem states that local operations on one particle do not alter remote statistical outcomes, maintaining zero mutual information ($I(X : Y) = 0$) via the unchanged reduced density matrix.
- The event-based framework treats the joint state as a single unified object. Local marginal statistics remain consistent with the theorem, while the single-shot deterministic manifestation (the "flop") is a property of the shared state itself.

2. **Special Relativity and Causality**
   - Relativity's light-speed limit (c) and spacetime interval preserve causality for propagating signals, avoiding paradoxes.
   - The framework uses non-local entanglement on a unified state, where nothing propagates. The instantaneous manifestation therefore does not involve a signal traveling faster than light; the constraints of STR simply do not apply in this domain.

Success of the hypothesis would not overturn established principles in their original domains. It would instead demonstrate that those principles are special cases of a more general operational description, refining our understanding without invalidating prior experimental confirmations.

9.3 Implications of the New Framework

If experimentally validated, the framework would open new pathways with far-reaching implications:

- **Scientific and Technological**: Enabling Instantaneous Manifestation of State Change could revolutionize telecommunications, computing, and distributed systems through non-local correlations.
- **Philosophical**: Redefining information as the detection of a structureless event links it directly to physical actions, extending beyond Shannon and Gabor's frameworks.
- **Broader Impact**: The *Independence Day* scene — where uncertainty gives way to collective resolve — serves as a metaphor for the transitional moment: from cautious adherence to traditional views toward an enlightened acceptance of non-local realities, while remaining grounded in empirical testing.

The new framework must continue to account for all existing data, including Bell tests, and address any apparent paradoxes through careful experimental design.

9.4 Critical Evaluation

The reformulation creatively navigates long-standing constraints by adopting a minimalist operational definition. Its validity ultimately hinges on the experimental confirmation of deterministic detection under the Operational Axiom. Paradigm shifts in physics, such as the transition to quantum mechanics, have historically arisen from anomalies that forced reevaluation of foundational assumptions. The event-based model could represent such a moment if the hypothesis stands the test of honest experiment. If experiments fail to confirm the axiom, it would reinforce established views. Partial or full success could enhance our understanding without requiring a complete overthrow of existing theory.

9.5 Conclusion

The event-based reformulation and the Operational Axiom of Entanglement signal a potential paradigm shift — the gradual relaxation of certain conservative interpretations and the emergence of a new operational framework that embraces non-local manifestation. While engaging with the no-signaling theorem and STR, it offers a concrete path for validation via QND and NV technologies. The perspectives of von Neumann, Einstein, Griffiths, and Monroe remain foundational; the framework simply does not adopt all of their assumptions as necessary in this domain. Like all previous scientific revolutions, the outcome will depend on empirical evidence and openness to new perspectives. Experimental timing of spin changes against delays will test these ideas and determine the true scope of the shift.

Chapter 10
The Arrow of Time and Instantaneous Manifestation

10.1 Introduction

The arrow-of-time is traditionally conceived as a directed progression from past to future, underpinning cause-effect relationships in physical theories. In the event-based framework, where manifestation occurs with zero temporal separation under the Operational Axiom of Entanglement (if experimentally validated), this directional vector collapses into a scalar point. This chapter reasons from first principles to examine this collapse, drawing on the event-based formalism where cause and effect coincide without delay. It builds on prior discussions of quantized information and event-based systems.

10.2 Statement

The arrow-of-time vector collapses to a scalar in events characterized by instantaneous manifestation. This collapse renders cause and effect equivalent, with no directional or magnitudinal separation, fundamentally altering the interpretation of temporal dynamics in physical processes.

10.3 Physical Meaning

The physical meaning centers on the instantaneity of manifestation, which collapses the arrow-of-time vector. The arrow-of-time, typically a directed vector from cause to effect with magnitude equal to elapsed time, reduces to a scalar point when the delay is zero. This implies cause and effect are equivalent, with no directional flow of time.

Consider the metaphorical insight from Sant Kabir:

> Ek Daal Do Panchi Baitha – Kaun Guru Kaun Chela
> Udd Jaa Hans Akela, Sant Kabir [Doha]

Quoting Sant Kabir, translated from Hindi, it says: Two Birds sitting on a branch, who is the Guru and who is the Shishya (Disciple) While Sant Kabir refers to the solitary nature of the soul and the impermanence of relationships — Udd Jaa Hans Akela — metaphorically — the Hans (The Bird Swan) — is the soul O Swan — Fly away alone

The Guru and the Shishya become interchangeable.

This illustrates the interchangeability: just as the guru and disciple lose distinction (no hierarchy or separation), cause and effect become interchangeable in the collapsed time vector. There is no "before" or "after" — the event is self-contained, mirroring instantaneous quantum processes like entanglement correlations.

10.4 Formalism

Let us formalize this concept using basic mathematical constructs derived from first principles.

Define the arrow-of-time as a vector $\mathbf{T}$ with direction from cause C to effect E and magnitude t, where t is the elapsed time:

$$\mathbf{T} = t \cdot \hat{d}_{C \to E}$$

In scenarios where manifestation is instantaneous (i.e., $t = 0$), the vector collapses:

$$\mathbf{T} \to 0$$

This results in a scalar representation $T = 0$, indicating no distinction between C and E:

$$C \equiv E$$

In event-based systems, this formalism applies to quantized information transfers, where each event is a discrete occurrence without temporal extension. The collapse enables recovery of classical temporal descriptions through aggregation of multiple events.

10.5 Key Verifications: Analysis and Verification

To verify this framework, consider the following analyses:

1. **Logical Consistency**: If manifestation is instantaneous, any temporal separation is illusory. The equivalence of cause and effect ensures self-consistency, as the event defines its own boundaries without external time references.
2. **Application to Quantum Entanglement**: In entangled systems, correlations manifest instantaneously across distances. The collapsed arrow-of-time explains this as a unified event, where measurement at one site is equivalent to the outcome at the other, aligning with observed non-local behavior.
3. **Recovery of Classical Regimes**: In macroscopic systems with observable time delays, the vector $\mathbf{T}$ retains non-zero magnitude, aggregating to probabilistic or continuous descriptions. This verifies extensibility to classical limits.

These verifications affirm the model's coherence through first-principles reasoning.

10.6 Conclusion

The analysis establishes that the arrow-of-time vector collapses to a scalar in events of instantaneous manifestation, unifying cause and effect. This perspective resolves temporal paradoxes in event-based theories, providing a minimalist framework for understanding information dynamics.

10.7 Implications

This framework has general implications for physics and information theory. It suggests reevaluation of constraints on phenomena involving temporal separation, as instantaneous equivalence bypasses traditional temporal barriers in the domain of the unified non-local state. It also bridges classical and quantum domains under a unified event-based approach, with potential extensions to cosmology, computation, and philosophical inquiries into time's nature.

Chapter 11
Implications for Causality and the Arrow of Time

11.1 Core Premise

The event-based theory of quantized information postulates that, under the Operational Axiom of Entanglement and if experimentally validated, information manifestation may occur instantaneously in systems using quantum entanglement. In such cases cause and effect occur with zero temporal separation.

11.2 The Collapse of the Arrow-of-Time Vector

When there is no passage of time between cause and effect, the arrow-of-time — traditionally conceived as a directed vector with direction from cause to effect and magnitude equal to the elapsed time — collapses to a scalar point with no direction. In other words, the Arrow-of-Time vector collapses to a dimensionless scalar point.

Sant Kabir's doha illustrates this insight poetically:

Ek Daal Do Panchi Baitha – Kaun Guru Kaun Chela
Udd Jaa Hans Akela

Translated from Hindi it says: Two birds sitting on a branch — who is the Guru and who is the Shishya (disciple)? O Swan — fly away alone.

Just as the guru and disciple lose hierarchical distinction on the same branch, cause and effect lose temporal separation in the collapsed arrow-of-time.

11.3 Implications of the Collapse of the Arrow-of-Time Vector

The collapse implies that the wavefunctions associated with cause and effect become interchangeable in the joint description. The claim of non-commutability of matrices in quantum mechanics therefore does not apply in this domain, along with its full set of consequences.

Considering the above: - The Arrow-of-Time vector collapses to a scalar point. - The wavefunctions of cause and effect become commutable. - The claim of non-commutability of matrices in quantum mechanics is not required in this domain.

The core implication is: - The chain of causality still exists but has no preferred direction in the instantaneous case. - The correlation between the Arrow-of-Time and increase in entropy becomes a macroscopic coincidence rather than an inevitable universal necessity.

11.4 Violation of the Causal Chain: Two Paradoxes Resolved

11.4.1 The Grandfather Paradox

The Grandfather Paradox states that if a person travels back in time and kills their own grandfather, they would never have been born. If they had never been born, how could they have killed their grandfather? This paradox has been taken to prohibit time travel.

The resolution is that the paradox is a logical fallacy. It makes the false assumption that the act must be repeatable, possibly infinitely. In reality, the act can occur only once. Once performed, the timeline is altered and the original actor no longer exists in the prior configuration. There is no necessity for repetition.

This fallacy is classified in the Navya Nyaya system (Gautama) as *bādhita* and in Aristotelian logic as *ignoratio elenchi*.

11.4.2 The Infinite Loop Paradox

The Infinite Loop Paradox states: if you travel to the past, then as time elapses and you reach the moment you first traveled, you will travel to the past again, creating an endless cycle.

The resolution again lies in free will. Nothing mandates that the same choice must be made again. The first decision was made under free will; the same freedom exists at every subsequent point. There is no inevitability forcing repetition.

This fallacy is classified in the Navya Nyaya system as *asiddha* and in Aristotelian logic as *petitio principii*.

11.5 Acknowledgement

I would like to acknowledge the fruitful discussion I had with Miss Riddhi Totla on the meaning of causality and the implications of both paradoxes. She resolved the Infinite Loop Paradox and provided valuable insights that led to the resolution of the Grandfather Paradox.

11.6 Conclusion

The collapse of the Arrow-of-Time vector to a scalar point is a direct logical consequence of zero-time manifestation under the Operational Axiom of Entanglement, if experimentally validated. Causality is preserved but loses its directional character in the instantaneous case. The framework does not claim to invalidate classical or relativistic causality in domains involving propagating signals; it simply operates in a domain where those assumptions are not required.

Chapter 12
Conclusion

This work has developed a minimalist event-based reformulation of information and a complete system blueprint for its manifestation. Information is reduced to the occurrence of a structureless binary event within a synchronized clock interval, and transmission is its reliable detection. In the quantum domain this becomes Instantaneous Manifestation of State Change (IMSC) under the single Operational Axiom of Entanglement.

The framework demonstrates that classical information theories and their physical constraints are recovered as special cases when the analysis is restricted to local marginals or ensemble averages. The constraints themselves are not violated or bypassed; they simply do not govern the domain defined by the unified non-local state.

The entire proposal is deliberately operational and engineering-oriented. It is built around commercially available components, synchronized clocks, redundant detection, and quantum non-demolition measurements. The next step is direct experimental validation of the Operational Axiom through timing of deterministic flop events in entangled systems.

If the axiom stands the test of honest experiment, it opens a new pathway for information manifestation while preserving the predictive power of existing physics in its original domains. The work is offered as a thought experiment and practical blueprint, inviting verification, critique, and refinement by the scientific community.
